

(57) Abstract
 Methods for introducing proteins or nucleotide sequences into the nucleus using a novel receptor-mediated delivery system. The delivery system includes a cell receptor-binding domain, a cytoplasmic translocation domain, and a nuclear translocation signal domain. This system can transport functional macromolecule that will act once internalized into the nucleus.

FIELD OF THE INVENTION
The invention relates to methods of introducing foreign materials into a cell nucleus. More particularly, the present invention discloses methods for transporting nucleotide sequences or proteins into the nucleus using a novel translocation signal or deficiency in the expression of certain necessary proteins required by a individual suffering from genetic diseases manifested by a augmentation with therapeutic doses of such proteins to lead normal lives. Currently, such treatment is mainly that of lifetime maintenance with periodic, exogenous introduction of the required protein. Such periodic treatment is cumbersome, expensive, and sometimes hazardous (such as for hemophiliacs who have a relatively high exposure rate to HIV).

It is desirable to utilize biomolecular manipulation to augment such protein deficiencies by introducing DNA (which code for the deficienit proteins). And other nucleotide sequences and polypeptides (which regulate the expression of the deficienit proteins) into the cells of patients suffering from hemophilia and adult respiratory distress syndrome (ARDS), hereditary emphysema or adult respiratory distress syndrome from VIII for hemophiliacs and adult respiratory distress syndrome from Such approaches can even be extended to re-transforn aberrant humor cells in cancer patients. The most attractive manner for achieving such therapeutic transformation is to deliver a gene coding for the deficienit gene product into the nucleus of somatic cells. In vitro delivery of foreign DNA into mammalian cells for gene expression has been achieved by three distinct approaches. The first approach takes advantage of the natural ability of viruses to infect cells and express viral DNA in the form of specific RNA and protein species (Comoy et al., 1991, "Gene transfer of adenovirus deaminase into primitive human hematopoetic progenitor cells", Human Gene Therapy, 2:203; Rosenberg et al., 1990, "Gene transfer into humans: immunotherapy of patients with advanced melanoma using infiltrating lymphocytes modified by et al.).

BACKGROUND

The invention relates to methods of introducing foreign materials into a cell nucleus. More particularly, the present invention discloses methods for transporting nucleotide sequences or proteins into the nucleus using a novel translocation signal or deficiency in the expression of certain necessary proteins required by a individual suffering from genetic diseases manifested by a augmentation with therapeutic doses of such proteins to lead normal lives. Currently, such treatment is mainly that of lifetime maintenance with periodic, exogenous introduction of the required protein. Such periodic treatment is cumbersome, expensive, and sometimes hazardous (such as for hemophiliacs who have a relatively high exposure rate to HIV).

It is desirable to utilize biomolecular manipulation to augment such protein deficiencies by introducing DNA (which code for the deficienit proteins). And other nucleotide sequences and polypeptides (which regulate the expression of the deficienit proteins) into the cells of patients suffering from hemophiliacs and adult respiratory distress syndrome (ARDS), hereditary emphysema or adult respiratory distress syndrome from VIII for hemophiliacs and adult respiratory distress syndrome from Such approaches can even be extended to re-transforn aberrant humor cells in cancer patients. The most attractive manner for achieving such therapeutic transformation is to deliver a gene coding for the deficienit gene product into the nucleus of somatic cells. In vitro delivery of foreign DNA into mammalian cells for gene expression has been achieved by three distinct approaches. The first approach takes advantage of the natural ability of viruses to infect cells and express viral DNA in the form of specific RNA and protein species (Comoy et al., 1991, "Gene transfer of adenovirus deaminase into primitive human hematopoetic progenitor cells", Human Gene Therapy, 2:203; Rosenberg et al., 1990, "Gene transfer into humans: immunotherapy of patients with advanced melanoma using infiltrating lymphocytes modified by et al.).

TITLE: TRANSLOCATION SIGNAL FACILITATED NUCLEAR DELIVERY OF MACROMOLECULES

WO 94/04696

retroviral gene transduction". New England Journal of Medicine, 323:570). In particular, advantage has been taken of mammalian retroviruses as vector systems that permit infection of a variety of cell types and allow for expression of many different foreign genes. Retroviruses and their recombinant forms are thought to bind to cells via specific receptors on the cell surface, after which they are internalized by endocytosis. Once endocytosed, the virus is able to evade immune surveillance by a mechanism which is thought to be endosome-lysosome pathway by a mechanism which is thought to be highly efficient, lipid-mediated DNA-transfection, "Lipofection": exogenous DNA with a cellular target (Fleigner et al., 1987, "Lipofection: A second approach uses artificial lipophilic vesicles containing nucleoli the endosome, escape degradation and permit entry into the cell nucleus. A third, non-specific approach for introduction of foreign DNA hypothesized that endosome- association may be bypassed. Hypothetic vesicle fusion is thought to be possible because it is highly efficient, lipid-mediated DNA-transfection via a highly efficient, lipid-mediated DNA-transfection procedure", Proc. Natl. Acad. Sci. USA, 84:7413). Delivery of DNA to the nucleus via a highly efficient, lipid-mediated DNA-transfection procedure", Proc. Natl. Acad. Sci. USA, 84:7413). Delivery of DNA to the nucleus via a highly efficient, lipid-mediated DNA-transfection procedure", Proc. Natl. Acad. Sci. USA, 84:7413). Delivery of DNA to the nucleus via a highly efficient, lipid-mediated DNA-transfection procedure", Proc. Natl. Acad. Sci. USA, 84:7413). Delivery of DNA to the nucleus via a highly efficient, lipid-mediated DNA-transfection procedure", Proc.

A second approach uses artificial lipophilic vesicles containing nucleoli the endosome, escape degradation and permit entry into the cell nucleus. A third, non-specific approach for introduction of foreign DNA hypothesized that endosome- association may be bypassed. Hypothetic vesicle fusion is thought to be possible because it is highly efficient, lipid-mediated DNA-transfection via a highly efficient, lipid-mediated DNA-transfection procedure", Proc.

10 A second approach uses artificial lipophilic vesicles containing nucleoli the endosome, escape degradation and permit entry into the cell nucleus. A third, non-specific approach for introduction of foreign DNA hypothesized that endosome- association may be bypassed. Hypothetic vesicle fusion is thought to be possible because it is highly efficient, lipid-mediated DNA-transfection via a highly efficient, lipid-mediated DNA-transfection procedure", Proc.

Hypothetic vesicle fusion is thought to be possible because it is highly efficient, lipid-mediated DNA-transfection via a highly efficient, lipid-mediated DNA-transfection procedure", Proc.

20 A second approach uses artificial lipophilic vesicles containing nucleoli the endosome, escape degradation and permit entry into the cell nucleus. A third, non-specific approach for introduction of foreign DNA hypothesized that endosome- association may be bypassed. Hypothetic vesicle fusion is thought to be possible because it is highly efficient, lipid-mediated DNA-transfection via a highly efficient, lipid-mediated DNA-transfection procedure", Proc.

25 A second approach uses artificial lipophilic vesicles containing nucleoli the endosome, escape degradation and permit entry into the cell nucleus. A third, non-specific approach for introduction of foreign DNA hypothesized that endosome- association may be bypassed. Hypothetic vesicle fusion is thought to be possible because it is highly efficient, lipid-mediated DNA-transfection via a highly efficient, lipid-mediated DNA-transfection procedure", Proc.

30 A second approach uses artificial lipophilic vesicles containing nucleoli the endosome, escape degradation and permit entry into the cell nucleus. A third, non-specific approach for introduction of foreign DNA hypothesized that endosome- association may be bypassed. Hypothetic vesicle fusion is thought to be possible because it is highly efficient, lipid-mediated DNA-transfection via a highly efficient, lipid-mediated DNA-transfection procedure", Proc.

35 A second approach uses artificial lipophilic vesicles containing nucleoli the endosome, escape degradation and permit entry into the cell nucleus. A third, non-specific approach for introduction of foreign DNA hypothesized that endosome- association may be bypassed. Hypothetic vesicle fusion is thought to be possible because it is highly efficient, lipid-mediated DNA-transfection via a highly efficient, lipid-mediated DNA-transfection procedure", Proc.

The exogenous DNA mixture with polyacrylic acid support or calcium phosphate is then incubated with live cells (i.e. a transfection step).

Uptake of endocytosis of DNA can be monitored by subsequent selection of the expressed phenotype, typically by complementation or by antibody-reactive surface markers. The mechanism of DNA uptake by the cells is largely unknown, but it is generally accepted that the DEAE-

activity of lysosomal cell compartments, followed by escape to the nucleus where expression occurs. Increased efficiency of expression using the transfection method can be achieved when lysosomotropic agents, such as chloroquine (Luthman et al., 1983, "High efficiency polyoma DNA transfection of chloroquine treated cells", Nuc. Acids Res., 11:1295), are included in the transfection mixtures. Lysosomotropic agents apparently reduce lysosomal destruction of DNA by increasing the relatively low pH necessary for activation of degradation.

(Curtet et al., 1991), "Adenoviruses enhancement of, transfectin-polylysine-mediated gene delivery", Proc. Natl. Acad. Sci. USA, 88:8850). Adenovirage was taken of the ability of the adenovirus particle to "uncap" its capsid proteins and permit early escape from the endosome-pathway. This group added adenoviruses particles to a

cytoplasma degeneration of the complex which appears another approach was provided by the observation that after infection of a host cell, adenovirus, like other viruses, evades intracellular destruction and targets its genome to the cell nucleus

cholaramphic acidyltransef erase (CAT) gene. Presentation of this complex to cells permitted uptake by asialoglycoprotein receptors and short term expression of the CAT gene (Wu et al., 1989). "Evidence for targeted gene delivery to HepG2 hepatoma cells *in vitro*". Biotechnology 27:887). However, the number of cells actually expressing the gene produced of interest was several orders of magnitude lower than the number endocytosing the complex, suggesting considerable intra-

Efforts have been made in the use of specific cell-surface receptors to mediate uptake of protein that is electrostatically coupled to a piece of DNA that is capable of expressing a gene product of interest. This was first made possible by the observation that a complex consisting of orosomucoid-coupled poly-L-lysine could bind by salt bridges a plasmid DNA that coded for the bacterial-derived human serum.

These problems include, but are not limited to the practical administration of a gene to an individual suffering from a particular disease amenable to therapy; targeting of the gene of interest to a particular cell-type or organ; efficient uptake of the gene by the cells; targeting of the gene to the nucleus; and efficient and sustained expression of the gene product. For example, while valuable as *in vitro* tools, retroviruses have considerable problems when used *in vivo*, including a very broad cell type specificity. The requirement for dividing cells to permit replication of the genome, inefficient expression of an inserted gene once in the nucleus, and questions of himan safety.

Thus, several *in vitro* methods have been proposed for introduction of foreign DNA into mammalian cells. However, these known methods have inherent drawbacks in use. In order to translate the *in vitro* approaches of gene expression to the problem of delivering therapeutic amounts of gene product, many problems and considerations have to be addressed.

The present invention is a translocation signal facilitated system for providing efficient, reproducible and targeted delivery of protein or DNA-protein complexes with therapeutic value. In the nuclei of mammalian cells, our approach takes advantage of the natural ability of some proteins, not just viruses, to enter cells and perform specific functions, such as directing their way out of endosomes into cytoplasm with the help of a cytoplasmic trans- location signal, and further directing them to the nucleus with the help of a specific nuclear targeting signal.

The present disclosure demonstrates cell specific targeting and intracellular translocation with exotoxin A of *Pseudomonas aeruginosa* which generally infects patients at the site of surface injury, but which primarily targets its virulence at fibroblast cells and systematically can also target the kidney to the liver, and secondarily to organs such as the spleen. Exotoxin A is composed of four domains, which are organized primarily into the amino terminus as domains Ia, II, Ib, and III (Allured

SUMMARY OF THE INVENTION

DNA in the range of a few kilobases to nearly fifty kilobases to mediate enhanced expression of, in this case, the product of the lufciferase gene (Cotteren et al., 1992). High-efficiency receptor-mediated delivery of small and large (48 kilobase) gene constructs using the endosome-disrupting activity of defecitve or hemiactivated adenoviruses particles", Proc. Natl. Acad. Sci. USA, 89:6094). Without added adenovirus capsids, expression of the luciferase gene was quite low, while with the adenovirus capsid, expression increased several orders of magnitude (Wagner et al., 1992). "Coupling of adenoviruses to transferin. polylysine/DNA complexes greatly enhances receptor-mediated gene delivery and expression of transfected genes", Proc. Natl. Acad. Sci. USA, 89:6099). However, even with viral capsid uncoating, transport of transferin-DNA complexes to the nucleus for expression is essentially random and introduces an element of uncertainty to such procedures. A major disadvantage of the adenovirus-facilitated gene delivery technique is that success relies on the tedious preparation of chemically-derived protein-DNA-virus complexes of unknown quality to achieve the enhanced levels of expression reported. A further drawback is the requirement of the coconcurrent expression of both transferin and adenoviruses receptors on the desired cell targets.

receptor-binding domain ("X") is domain Ia derived from the exotoxin. A binding domain, in the embodiment depicted in Figure 3, the mediated delivery of a target protein to a cellular receptor for the example, Figure 3 shows a schematic representation of a specific carrier-macromolecule that will act once internalized into the nucleus. By way "NTS", the nuclear translocation signal domain; and "Z", the functional receptor-binding domain; "II", the cytoplasmic translocation domain.

The critical features of the present delivery system are "X" the macromolecule to the nucleus for therapeutic intervention.

30 Preferred configuration of the critical domains needed for targeting a DNA or proteins is depicted in Figure 2. This figure shows the molecular system designed for the nuclear targeting and delivery of therapeutic use to the nuclei of cells. A schematic representation of the inadequate systems for delivering both genes and proteins of We describe a novel and efficient system that overcomes the transport of barece into the cytosol". Biochemistry, 31:3555).

25 "Translocation mediated by domain II of *Pseudomonas* exotoxin A: barece, to the cytoplasm of mammalian cells (Priot et al., 1992, used to deliver an unrelated domain, in this case, a bacterial nucleic acid also been demonstrated that exotoxin A domains Ia and II can be cytoplasm of certain cells for the purpose of cancer chemotherapy. It ADP-ribosylation domain III for targeting toxicity to the attachment of other non-toxin-related receptor-binding domains to the 20 cytosol. In addition, chimeric molecules can be constructed which allow uptake and delivery to the cell cytoplasm are described in Siegall et al., 1989, "Functional analysis of domains II, Ib and III of *Pseudomonas* exotoxin", J. Biol. Chem., 264:14256.

15 features of the exotoxin protein which are important for each step in its structural, rather than functional, domain (amino acids 365-404). The associated protein elongation factor 2; domain Ib appears to be a the ADP-ribosylating activity of the toxin that inactivates ribosome exotoxin out of the endosome; domain III (amino acids 405-613) contains compartment of the endosome and translocates the distal regions of the exotoxin that is specifically cleaved after activation in the low pH cell-surface receptor; domain II (amino acids 253-364) is the region of Domains Ia (amino acids 1-252) binds the exotoxin specifically to a Augerstrom resolution", Proc. Natl. Acad. Sci. USA, 83:1320 (Figure 1).

et al., 1986, "Structure of exotoxin A of *Pseudomonas aeruginosa* at 3.0-

nucleus, the polypeptide domain, in this case derived from β -translocation of the protein-carrier complex to the nucleus. Once in the nucleus, interacts with a cytoplasmic protein that promotes rapid of SV40 that is normally translated in the cytoplasm but functions in the nuclear targeting signal (NTS). In this case derived from a viral protein to the cytoplasm (see Figure 3). Once in the cytoplasm, the presence of a distal portion of the protein (part of domain II, NTS, and β -galactosidase)

the activation of this domain is the key to the translocation of the acidic, whereupon a pH-driven cleavage of domain II occurs, and it is the course of its maturation, the pH of the endosome becomes more endocytosis, and the complex becomes enfolded in endosomes. During the protein is internalized into the cell by

as fibroblasts, or to an organ such as the liver, by binding to a specific chimera to a particular cell type containing exotoxin A receptors such galactosidase. Domain Ia provides a natural means for directing the signal (NTS) from SV40 T-antigen, and a functional version of O-

domains Ia and II from *Pseudomonas* exotoxin A, a nuclear targeting amino terminus of the construct, the delivery system consists of

indoyl- β -D- galactopyranoside (X -gal) substrate. Starting from the development of blue color in the presence of 5-bromo-4-chloro-3-galactosidase, the nucleic acid delivery of which is measured by the *Pseudomonas* exotoxin A gene, and the functional domain ("Z") is B-

It is understood that there are many other different examples of polypeptide domains that bind DNA including poly-L-lysine and poly-D-lysine, repeats of nuclear translocation signal sequences ("poly-NTS"), or histidine, proline, spermidine, spermine, histones and other non-polyamino acid domains.

35

therapeutic proteins; if appropriate, replication of the targeted DNA followed by transcription and translation of RNAs coding for processes can unwind the DNA-binding domain from the DNA itself, translocation of the complex to the nucleus. Once translocated, the NTS domain binds to a cytoplasmic protein which mediates nucleus. The NTS domain binds to a cytoplasmic protein which mediates their respective binding proteins transport the NTS domains and truncated complex to the cytoplasm ensues, where the NTS domains and domain cleavage of domain II occurs and translocation of the dependent cleavage of domain II occurs and translocation of the endocytosis and internalization, and maturation of the endosome, pH delivery system-DNA complex molecule to a cellular receptor. After As described previously, domain Ia is used for binding of the

30

DNA molecule that codes for galactosidase. domain Ia derived from the *Pseudomonas exotoxin A* gene, domain II and poly-L-lysine which is used for electrostatic interaction with a plasmid the NTS domains are as described above, and domain "Z" is a stretch of domain Ia derived from the *Pseudomonas exotoxin A* gene, domain II and for DNA binding, in which the receptor-binding domain ("X") is designed to deliver nucleic acid (DNA) to a cell nucleus for gene delivery system shows the construction of a protein carrier to be used therapy. Figure 6 shows the construction of a protein carrier to be used

25

Figure 5 shows a pictorial representation of a protein carrier regulatory, transcribable gene that includes replication, oligonucleotide, or an expressible gene that includes replication, to a piece of DNA, comprising either a sense or antisense attached by electrostatic binding either specifically or non-specifically domain, but rather a DNA-binding domain. This DNA-binding domain is Figure 2 is that domain "Z" is no longer a functional polypeptide nuclease, the only modification of the chimeric construct described in nuclease, the purpose of delivering a nucleic acid, such as DNA, to the blood circulation.

The 2.3 kb DNA from Example 1 is used for polymerase chain reaction-mediated amplification of the binding (la) and cytoplasmic translocation (II) domains of the ETA gene. oligonucleotides GT105F (5'-GGATCCCTCATGAGCCGAGCGGAAGCTTCAACCTC) (SEQ. ID. NO. 1) and GT106R2 (5'-AAGCTTGTGCCCTGCCGAGCACGAGCCCT) (SEQ. ID. NO. 3) are used to amplify and for cloning DNA sequences coding for domains Ia and II, followed by downstream expression of the domains as non-secreted polypeptides in bacterial and insect cells.

58

Positive plagues are amplified for small-scale preparation of DNA which is recloned for easy manipulation into the Bluescript KS+ plasmid vector (Stratagene Corp., San Diego, CA). The 2.3 kilobase ETA genomic DNA is used as a source of template for further amplifications and modifications of different ETA domains.

EXAMPLE 2

GT103F (5'-GGATCCCTCACTGAGCCGCCAGGAGCCCTCGAACCTC (SEG, ID, NO, 1) and GT103R (5'-AAGCTTGGGAAAGTCAGGCCGATGACCTGAT) (SEG, ID, NO, 2) in the presence of digoxigenin-dUTP (Boehringer Mannheim Biochemicals, Indianapolis, IN). Positive plagues are amplified for small-scale preparation of DNA which is recommended for easy manipulation into the Bluescript KS+ plasmid vector (Stratagene Corp., San Diego, CA). The 2.3 kilobase E7A genomic DNA is used as a source of template for further amplifications and modifications of different E7A domains.

20

DNA is packaged into micelles using complementary packing extracts obtained from Stratagene Corp. (San Diego, CA). Approximately 1000 recombinant α particles are plated on indicator Esccherichia coli Y1090 and lifted onto nitrocellulose filters. DNA is lysed in situ as described in Mamatius et al., 1982. Molecular Cloning, A Laboratory Manual, Cold Spring Harbor, NY. Filters are then screened by hybridization with a DNA probe corresponding to the λ domain of *Pseudomonas exotoxin A* (ETA), prepared by PCR amplification of cleaved *Pseudomonas aeruginosa* PA103 DNA using oligonucleotides 15

10

agarose gel, from which a region of ~2 to 2.6 kilobase pairs is excised (the expected size of the exotoxin A gene segment is 2.3 kb, Gray et al., 1984). Cloning, nucleotide sequence, and expression in *Escherichia coli* of the exotoxin A structural gene of *Pseudomonas aeruginosa*, Proc. Natl. Acad. Sci. USA., 81:2645) and the DNA eluted. Purified Noul-EcoRI previously cleaved with Noul and EcoRI (Promega Corp., Madison, WI) in a reaction using T4 DNA ligase for 16 hours at 15°C.

10

WO 94/04696
PCT/US93/07945

Incorporated into the 5' ends of the oligonucleotides are restriction sites, BamHI and HindIII (underlined above) to facilitate downstream cloning and manipulation of domains. To achieve secretion of polypeptides having N-terminal domains Ia and II in the bacterial expression plasmid, PSE380 (Invitrogen Corporation, San Diego, CA), a second version of the clone is prepared using a forward oligonucleotide that primes within the DNA sequence coding for the Pseudomonas exotoxin A signal peptide sequence (GT001SF; TCACTGATACCCATTGGATTCCTG) (SEQ ID. NO. 4); for secretion in the insect cell expression system, a forward oligonucleotide (GT002SF; TCACTGATACCCATTGGATTCCTG) (SEQ ID. NO. 4); for baculoviruses insecticidic containing an insect-specific toxin gene", Nature, 352:85) is used (GT002SF).

In order to facilitate targeting of proteins or protein-DNA complexes to the nucleus, a cell-characterized nuclear translocation signal (NTS) domain from the mammalian virus, SV40 (Garcia-Bustos et al., 1991, "Nuclear protein localization" Biochemistry et Biophysica Acta, 1071:83) is included in the preparation of constituents.

Two overlapping synthetic oligonucleotides with complementary 5' HindIII restriction sites are used to prepare the SV40 NTS domain.

namely, GT108F; 5'-AGCTTCCCTAAGAGAACGTTAGCTCA (SEQ. ID. NO. 6).

and GT108R; 5'-AGCTTGACCTACGTTCTTCTTCTTCTGAA (SEQ. ID. NO. 7). Figure 7b shows amplified NTS domain produced by this method as a HindIII-Hind III SV40 end of ETA domains Ia and II. The position of the HindIII-Hind III SV40 NTS cassette relative to ETA Ia-II domain cassette is shown in Figure 7d.

EXAMPLE 4

Cloning of Escherichia coli lac Z gene

WO 94/04696
PCT/US93/07945

As a means of visually detecting proteins that are targeted to the nucleus, constructs are prepared that include an amino-terminal truncated version of the bacterial lac Z (lac Z) gene coding for B-galactosidase. This DNA segment was obtained by amplification of the lac Z gene-containing plasmid, PCH110 (Pharmacia, Piscataway, N.J.), using oligonucleotides GT107F (5'-AACCTTCAACGTCGTACCTGGCAAAACCCCTGGCGCTT) (SEQ-ID NO. 8) and GT107R (5'-CTGCCAGCTATTATTTGACACAGACCACTGGTAG) (SEQ-ID NO. 9). Figure 7c shows the lac Z gene sequence as a HindIII-PstI cassette.

EXAMPLE 5

Consisting of a Protein Carrier for Nuclear Delivery of a Target Protein, ETA domains Ia and II, the SV40 NTS domain, and the lac Z gene. The ETA Ia-II DNA cassette is ligated to the NTS and lac Z DNA cassette by T4 DNA ligase using the common HindIII restriction sites that are included within the PCR amplification primers. The final DNA construct is inserted into plasmid vectors for expression in the bacterium using recombinant baculoviruses. Techniques - A Journal of Methods in Cell and Molecular Biology, 2:173), or by expression in a

20 plasmids (for example, PV11393; Webb et al., 1990, "Expression of baculovirus system using one of several bacterial baculovirus expression plasmids (for example, PV11393; Webb et al., 1990, "Expression of

25 bacteria by infection into a high expression plasmid vector, like PET, which uses T7 promoter-specific expression (Studier et al., 1986, "Use of bacteriophage T7 RNA polymerase to direct selective high-level expression of cloned gene", J. Mol. Biol., 189:113).

30 Protein constructs expressed in either baculoviruses or bacteria are purified from cell lysates and/or media over anti-B-galactosidase antibody columns linked via protein A. Proteins thus prepared are

35 suitable for targeting for functional analysis. A-sensitivity mammalian nucleus by in vitro incubation with exotoxin A-sensitizing agent CCL 12 or CCL 13) and/or Chag liver cells, American Type Culture Collection CCL 12 or CCL 13) and/or after injection into the mammalian blood circulation for in vivo targeting to either the liver and/or secondary organs.

Successfull nuclear targeting is assayed histochimically by the conversion of the colorless X-gal substrate to blue, indicating functional

domains are the HindIII and PstI restriction sites that are also used for coding for these domains, included at the 5' and 3' ends of the amplified domains are amplified by the PCR from genomic DNA or from cDNA sequences, for example, homeobox domains of yeast GAL4 protein. These derived from any of several nuclear proteins that bind specific DNA binding protein domain (domain "Z"). This polypeptide domain is 35 Figure 11 shows an alternative method for preparing a DNA sequence.

Construction of ETA domains Ia and II/ NTS / DNA binding protein

35

EXAMPLE 7

As a further alternative to incorporating polyacetylation substitutions expressed ETA IA-II-NTS core construct in order to achieve a similar coupled by chemical modification to a bacterial or baculovirus it will be appreciated that polylysine, for example, can be covalently for the β -galactosidase domain as continuous translation products. As a further alternative to incorporating polyacetylation substitutions (refer to Figure 7d).

As an alternative to the use of polylysine, a DNA segment containing as many as 20-30 NTS repeats derived from the SV40 sequence (since the SV40 nucleolar targeting signal is polyacetylic), or a smaller number of repeats if they are derived from other longer nucleic targeting signals, can be used (Figure 9). Any one of these different polyacetylic segments can be ligated at the 3' end of the core construct consisting of ETA IA-II/ NTS (BamHI-HindIII) cassette expressed ETA IA-II-NTS core construct in order to achieve a similar effect (Figure 10).

25

As an alternative to the use of polylysine, a DNA segment proximal to the PstI site is placed a stop codon like TAG, TGA or TAA to restriction site at its 5' end and a PstI site at its 3' end (as in, lac Z). Just - 300 bases of poly AAA/AAG (lysine codons) containing an HindIII polypeptide segment is generated from a synthetic DNA segment of ~200 example, we use poly-L-lysine as the polyacetylation stretch. A polylysine polypeptide that has a polyacetylation stretch at the "Z" domain. In this Figure 8 shows the preferred configuration for a continuous

20

Construction of ETA domains Ia and II/ NTS / catalytic polypeptide

10

EXAMPLE 6

β -galactosidase. Similar constructs can be prepared for use with other domains substituted for β -galactosidase and/or ETA Ia domains.

35

The formation of protein-DNA complexes is determined by gel Tris-HCl, pH 7.5, 1 mM EDTA and diluted down to 150 mM NaCl by dialysis. PCH110, a commercially available mammalian expression plasmid coding for D-galactosidase (Pharmacia, Piscataway, NJ), in 2M NaCl, 10 mM phosphate-buffered saline.

30

The resultant purified protein carrier is then incubated with (N-hydroxysuccinimide) chemistry. Uncomplexed poly-L-lysine is removed by chromatography over Sephadex G-100 (or its equivalent) in then coupled to the ETA IA-II / NTS domain by using conventional NHS basic proteins. Commercially available poly-L-lysine (40,000 mol. wt.) is exchanged column such as carboxymethyl-Sephadex, that will bind media by conventional ion exchange chromatography over an anionic expressed protein carriers are purified from cell lysates and/or high-level expression of cloned gene". J. Mol. Biol. 189:113).

25

al., 1986, "Use of bacteriophage T7 RNA polymerase to direct selective vector, like PET, which uses T7 promoter-specific expression (Studier et al. 1990, "Expression of proteins using recombinant baculoviruses", Techniques - A Journal of Methods in Cell and Molecular Biology, 2:173).

 (iv) SEQUENCE DESCRIPTION: SEQ ID NO: 9
 (i) SEQUENCE CHARACTERISTICS:
 (10) INFORMATION FOR SEQUENCE ID NO: 9

We Claim:

1. A composition comprising a polypeptide which contains a receptor-binding domain, a cytoplasmic translocation domain, a nucleic acid translocation domain, and a means for connecting a selected polypeptides, and proteins, a nucleotide sequence of nucleotides, selected from the group consisting of nucleotides, oligopeptides, galactosidase.
2. The composition of Claim 1 wherein the said macromolecule is selected from the group consisting of Claim 1 wherein the said macromolecule to the said polypeptide.
3. The composition of Claim 1 wherein the said receptor-binding domain is a toxin-derived ligand for a specific cell receptor, is derived from diphtheria toxin, or from *Pseudomonas exotoxin A*.
4. The composition of Claim 1 wherein the said cytoplasmic translocation domain is derived from *Pseudomonas exotoxin A*.
5. The composition of Claim 1 wherein the said nucleic acid sequence, yeast alpha-2 nucleic acid sequence, and GAL-4 nucleic acid sequence, yeast alpha-2 nucleic acid sequence, and GAL-4 nucleic acid sequence.
6. The composition of Claim 1 wherein the means for connecting the macromolecule to the nucleic translocation domain is a polyacetylene which is selected from the group consisting of SVA40 nucleic acid sequence, poly-D-Lysine, poly NTs, ornithine, putrescine, a histone, GAL-4, Lysine, poly-D-Lysine, poly NTs, ornithine, putrescine, a histone, GAL-4, a homeobox domain, spermidine, and spermine.
7. A method for inserting an exogenous macromolecule into a target cell nucleus comprising the steps of:
 - a) administering a polypeptide which contains a receptor-binding domain, a cytoplasmic translocation domain, a nucleic acid translocation domain, and a means for connecting a selected macromolecule to the said polypeptide, to target cells
 - b) incubating cells with said polypeptide, and
 - c) determining transfer by an assay.
8. The method as in Claim 7 wherein the polypeptide is as described by Claim 2, Claim 3, Claim 4, Claim 5, or Claim 6.
